Summary

Perturbative
breakdown &
nonlocality

Suvrat Raju

Empty AdS

Perturbation
theory and
locality

String
amplitudes

Information
Paradox

- Generally accepted that locality breaks down in quantum gravity at the Planck scale

$$[\phi(t, \mathbf{x}), \phi(t, \mathbf{x} + \vec{\ell}_{\text{pl}})] = ?$$

- In this talk, we will argue that for some observables, **nonlocal effects in gravity spread out over macroscopic distances.**

Summary

Perturbative
breakdown &
nonlocality

Suvrat Raju

Empty AdS

Perturbation
theory and
locality

String
amplitudes

Information
Paradox

- Observables sensitive to these nonlocal effects are **very high point correlators**. For example

$$\langle [\dot{\phi}(t, \mathbf{x}_1), \phi(t, \mathbf{x}_2) \dots \phi(t, \mathbf{x}_n)] \rangle \neq 0,$$

even for spacelike $|\mathbf{x}_i - \mathbf{x}_j| \gg \ell_{\text{pl}}$ for **sufficiently large** n .

- This happens because the algebra of local observables in gravity **satisfies polynomial constraints**

$$\phi(t, \mathbf{x}_1) \cong \mathcal{P}(\phi(t, \mathbf{x}_2), \dots, \phi(t, \mathbf{x}_n)).$$

Similar to **black hole complementarity**.

- This has significant implications for the **information paradox**.

Overview

Perturbative
breakdown &
nonlocality

Suvrat Raju

Empty AdS

Perturbation
theory and
locality

String
amplitudes

Information
Paradox

- 1 Complementarity in empty AdS
- 2 Perturbation theory and locality
- 3 String perturbation theory for many external particles
- 4 Information Paradox

Empty AdS Complementarity

Perturbative
breakdown &
nonlocality

Suvrat Raju

Empty AdS

Perturbation
theory and
locality

String
amplitudes

Information
Paradox

The idea of complementarity \Leftrightarrow high-order polynomial constraints between local operators can be realized precisely in empty anti-de Sitter space.

Empty AdS Complementarity

Operator at center of AdS can be written as complicated polynomial of operators that are uniformly spatially separated!

Perturbative
breakdown &
nonlocality

Suvrat Raju

Empty AdS

Perturbation
theory and
locality

String
amplitudes

Information
Paradox

Implications of Reeh-Schlieder

Perturbative
breakdown &
nonlocality

Suvrat Raju

Empty AdS

Perturbation
theory and
locality

String
amplitudes

Information
Paradox

$$\phi(0) = \sum_{n,m \ll N} c_{nm} |n\rangle \langle m|.$$

Use version of the **Reeh-Schlieder** theorem to write

$$|n\rangle = X_n[\phi(C)]|0\rangle,$$

where X_n is a **simple polynomial**.

Vacuum projector

Perturbative
breakdown &
nonlocality

Suvrat Raju

Empty AdS

Perturbation
theory and
locality

String
amplitudes

Information
Paradox

- H is a boundary term in gravity. So

$$P_0 = |0\rangle\langle 0| = \lim_{\alpha \rightarrow \infty} e^{-\alpha H},$$

is an operator in \mathcal{C} .

- Can approximate P_0 by a **very complicated polynomial in \mathcal{C}**

$$P_0 \approx \mathcal{P}[\phi(\mathcal{C})] = \sum_{n=0}^{n_c} \frac{(-\alpha_c H)^n}{n!}.$$

- With

$$\alpha_c = \log N; \quad n_c = N \log(N),$$

\mathcal{P} is a good approximation to P_0 .

Empty AdS Complementarity

Perturbative
breakdown &
nonlocality

Suvrat Raju

Empty AdS

Perturbation
theory and
locality

String
amplitudes

Information
Paradox

Combining the previous formulas we get

$$\phi(0) = \sum_{n,m \ll N} c_{nm} X_n[\phi(C)] \mathcal{P}[\phi(C)] X_m^\dagger[\phi(C)]$$

where X_n are simple polynomials, and \mathcal{P} is a complicated polynomial. **Explicitly realizes idea of complementarity** and also **consistent with approximate locality**.

Lessons from AdS

Perturbative
breakdown &
nonlocality

Suvrat Raju

Empty AdS

Perturbation
theory and
locality

String
amplitudes

Information
Paradox

- The root of this nonlocality lies in the Gauss law

$$i[H, \phi(t, \mathbf{x})] = \dot{\phi}(t, \mathbf{x}).$$

- For canonically normalized operators, Gauss law leads to $\frac{1}{N}$ -suppressed commutators.

$$i\left[\int h^{00} d^{d-2}\Omega, \phi(t, \mathbf{x})\right] = \frac{1}{N}\dot{\phi}(t, \mathbf{x}).$$

- These $\frac{1}{N}$ effects are enhanced to $O(1)$ effects by the **breakdown of $\frac{1}{N}$ -perturbation theory.**

Flat Space

Perturbative
breakdown &
nonlocality

Suvrat Raju

Empty AdS

Perturbation
theory and
locality

String
amplitudes

Information
Paradox

- Hamiltonian is a boundary term even in flat space.

$$H = M_{\text{pl}}^{\frac{d-2}{2}} \int_{\infty} d^{d-2} \Omega n^k (h_{ik,i} - h_{ii,k}).$$

- Leads to nonlocal commutators suppressed by power of $\frac{E}{M_{\text{pl}}}$ ← gravitational coupling constant.
[Donnelly, Giddings, 2016]
- In flat space, the breakdown of gravitational perturbation theory for high-point correlators may signal the loss of locality for such observables.
- The relation between loss of locality and perturbative breakdown in gravity is also natural from the path-integral viewpoint.

Breakdown of String Perturbation Theory

Perturbative
breakdown &
nonlocality

Suvrat Raju

Empty AdS

Perturbation
theory and
locality

String
amplitudes

Information
Paradox

This is the motivation to study the behaviour of string perturbation theory for many external particles.

String perturbation theory breaks down for a large number of external particles, even if the energy per particle stays small.

String Perturbation Theory Limits

- Consider limit where string and Planck scale are widely separated, n is large, and energy-per-particle is small.

$$g_s^2 = \frac{2\pi l_{pl}^{d-2}}{(2\pi\sqrt{\alpha'})^{d-2}} \rightarrow 0, \quad n \rightarrow \infty,$$

$$\frac{\log(E\sqrt{\alpha'})}{\log(n)} \rightarrow -\gamma, \quad 0 < \gamma < \frac{1}{(d-2)}.$$

- String perturbation theory breaks down **at least at**

$$\frac{\log(g_s)}{\log(n)} = \frac{1}{2}((d-2)\gamma - 1) + O\left(\frac{1}{\log(n)}\right),$$

or

$$n \propto g_s^{\frac{-2}{1-(d-2)\gamma}} \Rightarrow n \propto \left(\frac{M_{pl}}{E}\right)^{d-2}$$

Unitarity Bounds vs Factorial Growth

Perturbative
breakdown &
nonlocality

Suvrat Raju

Empty AdS

Perturbation
theory and
locality

String
amplitudes

Information
Paradox

- Within perturbation theory, tree amplitudes must satisfy

$$\int d\Pi_{\frac{n}{2}} \left| M^{\text{tr}}\left(\frac{n}{2} \rightarrow \frac{n}{2}\right) \right|^2 \leq 2 \left| M^{\text{tr}}\left(\frac{n}{2} \rightarrow \frac{n}{2}\right) \right|.$$

- Tree-level string **tree amplitudes grow as**

$$M^{\text{tr}} \propto g_s^{n-2} n!$$

- Factorial growth violates **unitarity bounds at**

$$n \propto \left(\frac{M_{\text{pl}}}{E} \right)^{d-2}.$$

String Amplitudes using Punctured Spheres

Perturbative
breakdown &
nonlocality

Suvrat Raju

Empty AdS

Perturbation
theory and
locality

String
amplitudes

Information
Paradox

- Usually, tree amplitudes are formulated as integrals over the positions of $(n - 3)$ vertex operators on the round sphere.
- Rewrite as integrals over the **moduli space of a n -punctured sphere** with uniform negative curvature, $R = -1$. eg., in the bosonic string

$$M^{\text{tr}} = g_s^{n-2} \int_{\mathcal{M}_n} d\mu_{\text{WP}} (\det P_1^\dagger P_1)^{\frac{1}{2}} (\det \Delta)^{\frac{-d}{2}} \langle V_1 \dots V_n \rangle.$$

[D'Hoker, Giddings, Sonoda, 1987]

$[\alpha' = 2]$

Volume of Moduli Space

Perturbative
breakdown &
nonlocality

Suvrat Raju

Empty AdS

Perturbation
theory and
locality

String
amplitudes

Information
Paradox

- We argue that the main contribution to the amplitude comes from the **volume of moduli space**. [**Caution: some hand-waving involved.**]

$$V_{g,n} = \int_{\mathcal{M}_{g,n}} d\mu_{\text{WP}}.$$

- Builds on earlier arguments that $V_{g,0}$ dominates the partition function at genus g .
[**Gross, Periwal, D'Hoker, Phong, 1988**]
- Volumes of Weil-Petersson moduli spaces have received significant attention in the Mathematical literature.

Volume of Moduli Space

Perturbative
breakdown &
nonlocality

Suvrat Raju

Empty AdS

Perturbation
theory and
locality

String
amplitudes

Information
Paradox

- For any fixed n and large g

$$V_{g,n} \rightarrow (4\pi^2)^{2g+n-3} (2g+n-3)! \frac{1}{\sqrt{g\pi}} \left(1 + \mathcal{O}\left(\frac{1}{g}\right) \right).$$

[Zograf, Mirzakhani, 2008–2013]

- At $n = 0$, $g \rightarrow \infty$, obtain famous $(2g)!$ growth of string-amplitudes.

[Shenker, 1991]

- At large $g + n$

$$\frac{\log(V_{g,n})}{(n+2g) \log(n+2g)} \rightarrow 1.$$

With $g = 0$

$$V_{0,n} \propto n!$$

Numerical Analysis of String Amplitudes

Perturbative
breakdown &
nonlocality

Suvrat Raju

Empty AdS

Perturbation
theory and
locality

String
amplitudes

Information
Paradox

We can verify the $n!$ growth through a numerical analysis of string amplitudes at large n .

Scattering Equations

Perturbative
breakdown &
nonlocality

Suvrat Raju

Empty AdS

Perturbation
theory and
locality

String
amplitudes

Information
Paradox

- At large n , the integral over moduli space localizes to solutions of the **scattering equations**

$$\sum_{j \neq i} \frac{k_i \cdot k_j}{z_i - z_j} = 0, \forall i.$$

[Gross, Mende, 1987]

[Cachazo, He, Yuan, 2013]

- Exactly $(n - 3)!$ solutions \Rightarrow exactly one saddle point per unit volume of moduli space.

Monte Carlo Numerical Algorithm

Perturbative
breakdown &
nonlocality

Suvrat Raju

Empty AdS

Perturbation
theory and
locality

String
amplitudes

Information
Paradox

- Find **random solutions** of the scattering equations, and evaluate string-integrand, I_{str} , at these solutions. Then use

$$M^{\text{tr}} = (n - 3)! \langle I_{\text{str}} \rangle.$$

[**Caution: random sampling may underestimate true answer**]

- Procedure works both for the **type II superstring** and the **bosonic string**.
- We examined about 4×10^7 solutions of scattering equations for $n = 4 \dots 100$. Takes about 8,000 hours of CPU time (Xeon E5@2.5GHz).

Numerical results: Superstring

Perturbative
breakdown &
nonlocality

Suvrat Raju

Empty AdS

Perturbation
theory and
locality

String
amplitudes

Information
Paradox

$$\begin{aligned}\log(\tilde{M}_n) &= \log(M_n^{\text{tr}}) - (n-2)\log(4\pi g_s) + n\log(d-2) \\ &= a + bn + \log((n-3)!).\end{aligned}$$

Numerical results: Bosonic String

Perturbative
breakdown &
nonlocality

Suvrat Raju

Empty AdS

Perturbation
theory and
locality

String
amplitudes

Information
Paradox

Factorial growth is an **excellent fit** both for the bosonic string and the superstring.

Implications for the Information Paradox

Perturbative
breakdown &
nonlocality

Suvrat Raju

Empty AdS

Perturbation
theory and
locality

String
amplitudes

Information
Paradox

The loss of locality suggested by this perturbative breakdown is precisely sufficient to resolve some versions of the information paradox.

Information Release in Hawking Radiation

Perturbative
breakdown &
nonlocality

Suvrat Raju

Empty AdS

Perturbation
theory and
locality

String
amplitudes

Information
Paradox

- The von Neumann entropy of the emitted black-hole radiation varies with time as follows

[Page, 93]

- Information starts to exit the black hole **after the Page time.**

Cloning Paradox

Perturbative
breakdown &
nonlocality

Suvrat Raju

Empty AdS

Perturbation
theory and
locality

String
amplitudes

Information
Paradox

- The black-hole spacetime can then be foliated with nice slices. Information seems both outside and inside:

$$|\Psi\rangle \rightarrow |\Psi\rangle \otimes |\Psi\rangle?$$

[Susskind, Thorlacius, Uglum, 93]

Strong Subadditivity Paradox

Perturbative
breakdown &
nonlocality

Suvrat Raju

Empty AdS

Perturbation
theory and
locality

String
amplitudes

Information
Paradox

$$C : r_h - \delta < r < r_h;$$

$$B : r_h < r < r_h + \delta;$$

$$A : r_h + \delta < r < \infty.$$

After the Page time, new radiation in B is entangled with A ,
and **also** with C . Violates strong subadditivity of entropy:

$$S_A + S_C \leq S_{AB} + S_{BC}.$$

[Mathur, AMPS, 2009–12]

Measurement Protocols

Perturbative
breakdown &
nonlocality

Suvrat Raju

Empty AdS

Perturbation
theory and
locality

String
amplitudes

Information
Paradox

- It is difficult to **extract information** or **measure the von Neumann entropy** of Hawking radiation due to the following theorem:

$$\int \langle \Psi | A | \Psi \rangle d\mu_\psi = \text{Tr}(\rho A),$$

$$\int (\langle \Psi | A | \Psi \rangle - \text{Tr}(\rho A))^2 d\mu_\psi = \frac{(\text{Tr}(\rho A^2) - (\text{Tr} \rho A)^2)}{e^S + 1},$$

with $\rho = e^{-S} \mathbf{I}$. **But $S_\rho = S$ while $S_{|\Psi\rangle} = 0$.**

- This theorem can be beaten by measuring e^S observables.
- Need some order **S-point correlators of Hawking radiation** to detect cloning/strong subadditivity violation.

Perturbative Breakdown in Information Extraction

Perturbative
breakdown &
nonlocality

Suvrat Raju

Empty AdS

Perturbation
theory and
locality

String
amplitudes

Information
Paradox

- Corresponds to S-matrix elements with S -insertions and typical momentum of order T

- But perturbation theory breaks down for

$$\frac{(2-d) \log \frac{T}{M_{\text{pl}}}}{\log(n)} = 1 + \mathcal{O}\left(\frac{1}{\log(n)}\right).$$

Reached **precisely** at $n = S$.

- So S -point correlators **receive non-perturbative corrections**. Also possibly sensitive to **nonlocal effects**.

Black Hole Complementarity

Perturbative
breakdown &
nonlocality

Suvrat Raju

Empty AdS

Perturbation
theory and
locality

String
amplitudes

Information
Paradox

- Our proposal to avoid cloning is to **identify operators outside and inside** through

$$\phi(x_{in}) \cong P(\phi(x_2), \phi(x_3), \dots, \phi(x_S)).$$

Version of **complementarity**.

- **Locality is lost, but no cloning.**

Complementarity and Strong Subadditivity

Perturbative
breakdown &
nonlocality

Suvrat Raju

Empty AdS

Perturbation
theory and
locality

String
amplitudes

Information
Paradox

If $\phi(x_C) \cong P(\phi(x_{A_1}), \phi(x_{A_2}), \dots, \phi(x_{A_S}))$,
the algebra of the theory does **not** factorize.

$$\mathcal{A} \neq \mathcal{A}_A \otimes \mathcal{A}_B \otimes \mathcal{A}_C \otimes \bar{\mathcal{A}}.$$

So, strong subadditivity inapplicable.

Toy Model of the Information Paradox

Perturbative
breakdown &
nonlocality

Suvrat Raju

Empty AdS

Perturbation
theory and
locality

String
amplitudes

Information
Paradox

Divide a constant time slice of global AdS, into three regions, A,B,C.

- In empty AdS: $\phi(x_C) = \mathcal{P}(\phi(x_{A_1}), \phi(x_{A_2}), \dots, \phi(x_{A_N}))$.
- Information in C is also in A — **cloning?**
- B is entangled with both C and A — violation of **monogamy of entanglement?**
- In empty AdS, **clear** that paradoxes are resolved through a subtle **loss of locality**.

Summary

- In empty AdS, we can **explicitly** rewrite a local operator as a complicated polynomial of other spacelike-separated local operators: $\phi(0) = \sum_{n,m} c_{nm} X_n P_0 X_m^\dagger$.
- Relies on the **Gauss law** and **breakdown of $\frac{1}{N}$ perturbation theory** for correlators with $O(N)$ insertions.
- Motivates study of limits on flat-space string perturbation theory.
- With small E , large n , provided evidence that string perturbation theory breaks down at least at $n \propto \left(\frac{M_{\text{pl}}}{E}\right)^{d-2}$.
- Limit is **precisely met** for $n = S$, and $E = T$ of a black hole.
- Suggests an elegant resolution to the cloning/strong subadditivity paradoxes: subtle loss of locality for $O(S)$ -point correlators.
